AB The present invention discloses a novel and general process to prepare various pyridine substituted 5-[4-[2-(alkyl substituted pyridyl)ethoxy]benzyl]-2,4-thiazolidinone derivs. of general formula I [R = alkyl], and their pharmaceutically acceptable salts. The present invention especially provides a novel process to prepare pioglitazone hydrochloride [R = 5-ethyl], via novel intermediates, i.e. II and III. This process involves lesser number of steps with high yields and uses key solid intermediates, which are operationally simple, and therefore offers opportunities for better com. viability.

AB The authors have developed improved syntheses of pioglitazone metabolites I, II, III, and IV and the putative metabolite ketone V. These entities have been compared in the KKAy mouse model of human type-II diabetes to pioglitazone. Ketone V has proven to be the most potent of these thiazolidinediones in this in vivo assay. When I-V were compared in vitro in the 3T3-L1 cell line to pioglitazone for their ability to augment insulin-stimulated lipogenesis, V was again the most potent compound with I,

II, and IV roughly equivalent to pioglitazone. These data suggest that metabolites I, II, and IV are likely to contribute to the pharmacol. activity of pioglitazone, as had been previously reported for ciglitazone..

AB The present invention relates to thiazolidinedione analogs that are useful for treating inflammatory disease. In general, the invention relates to pharmaceutical compns. comprising a combination of glucocorticoid agonists and insulin sensitizers that have reduced activation of the nuclear transcription factor PPARγ. Thus, pharmaceutical composition including a thiazolidinedione analogs can be produced by tableting between 1 mg to 200 mg thiazolidinedione analog, CM-cellulose or carmellose, magnesium stearate, hydroxypropyl cellulose, and lactose monohydrate.

AB In accordance with the purpose of the invention, as embodied and broadly described herein, the invention is broadly drawn to a new method of treatment, the use of agents to manufacture a composition of treatment or the composition of treatment for the prevention of rapidly progressive puberty, the prevention of early menarche or the modulation, more particularly the delay, of the tempo of puberty in a female mammal, preferably a human girl, and the disorders related thereto. In a particular embodiment the present invention involves the use of at least one insulin-sensitizing agent such as metformin, any of the polymorphs of metformin or a pharmaceutically acceptable salt thereof for the preparation of a composition of treatment to modulate the tempo of pubertal progression in a girl. Metformin administration to girls experiencing precocious puberty resulted in normalization of pubertal progression to menarche, increased height gains, leaner body composition, and decreases indexes relating to insulin resistance.

PUBLISHER: Blackwell Publishing Ltd.
DOCUMENT TYPE: Journal
LANGUAGE: English
AB Our objective was to identify the cytochrome P 450 (CYP) enzymes that metabolize pioglitazone and to examine the effects of the CYP2C8 inhibitors montelukast, zafirlukast, trimethoprim and gemfibrozil on pioglitazone metabolism in vitro. The effect of different CYP isoform inhibitors on the elimination of a clin. relevant concentration of pioglitazone (1 μM) and the formation of the main primary metabolite M-IV were studied using pooled human liver microsomes. The metabolism of pioglitazone

by CYP1A2, CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP2D6, CYP2E1, CYP3A4 and CYP3A5 was investigated using human recombinant CYP isoforms. In particular, the inhibitors of CYP2C8, but also those of CYP3A4, markedly inhibited the elimination of pioglitazone and the formation of M-IV by HLM. Inhibitors selective to other CYP isoforms had a minor effect only. Of the recombinant isoforms, CYP2C8 (20 pmol/mL) metabolized pioglitazone markedly (56% in 60 min.), and also CYP3A4 had a significant effect (37% in 60 min.). Montelukast, zafirlukast, trimethoprim and gemfibrozil inhibited pioglitazone elimination in HLM with IC50 values of 0.51 μM, 1.0 μM, 99 μM and 98 μM, resp., and the formation of the metabolite M-IV with IC50 values of 0.18 μM, 0.78 μM, 71 μM and 59 μM, resp. In conclusion, pioglitazone is metabolized mainly by CYP2C8 and to a lesser extent by CYP3A4 in vitro. CYP2C9 is not significantly involved in the elimination of pioglitazone. The effect of different CYP2C8 inhibitors on pioglitazone pharmacokinetics needs to be evaluated also in vivo because, irresp. of their in vitro CYP2C8 inhibitory potency, their pharmacokinetic properties may affect the extent of interaction.

AB A HPLC-MS method was established for simultaneous determining of pioglitazone and its two active metabolites: M-III (keto-derivative) and M-IV (hydroxy-derivative) in human plasma. The separation was performed on a Waters XTerraTM C18 column (2.1 mm+150 mm, 3.5 μm) with guard column Phenomenex C18. The column temperature was 50 degree. The mobile phase consisted of acetonitrile-30 mmol·L-1 ammonium acetate solution (added with 0.1% formic acid and 0.05% trifluoroacetic acid) (35:65), with a flow rate of 0.22 mL·min-1. The compound was ionized in the electrospray ionization (ESI) ion source of the mass spectrometer and selected ion mass spectral (m/z) 357.4 (PIO), 358.2 (is), 371.5 (M-III), 373.2 (M-IV) to quantify. Human plasma samples were extracted with 1:2 chlorform:methyl t-Bu ether after acidification. The linear ranges were 11.16-1748.60 ng·mL-1 for pioglitazone, 3.33-520.50 ng·mL-1 for M-III and 5.00-687.50 ng·mL-1 for M-IV (r≥0.9997), and their detect limits were 2.90, 1.10, 1.20 ng·mL-1. Recoveries were within 90%-110%, and intra-and inter-day RSDs were all less than 15%. The method is found to be sensitive, rapid and accurate, and has been applied successfully to sample anal. for clin. study of pioglitazone pharmacokinetics and drug interaction.

AB Aims The effect of enzyme induction on the pharmacokinetics of pioglitazone, a thiazolidinedione antidiabetic drug that is metabolized primarily by CYP2C8, is not known. Rifampicin is a potent inducer of several CYP enzymes and our objective was to study its effects on the pharmacokinetics of pioglitazone in humans. Methods In a randomized, two-phase crossover study, ten healthy subjects ingested either 600 mg rifampicin or placebo once daily for 6 days. On the last day, they received a single oral dose of 30 mg pioglitazone. The plasma concns. and cumulative excretion of pioglitazone and its active metabolites M-IV and M-III into urine were measured up to 48 h. Results Rifampicin decreased

the mean total area under the plasma concentration-time curve (AUC0-∞) of pioglitazone by 54% (range 20-66%; P = 0.0007; 95% confidence interval -78 to -30%) and shortened its dominant elimination half-life (t1/2) from 4.9 to 2.3 h (P = 0.0002). No significant effect on peak concentration (Cmax) or time to peak (tmax) was observed Rifampicin increased the apparent formation rate of M-IV and shortened its tmax (P < 0.01). It also decreased the AUC0-∞ of M-IV (by 34%; P = 0.0055) and M-III (by 39%; P = 0.0026), shortened their t1/2 (M-IV by 50%; P = 0.0008, and M-III by 55%; P = 0.0016) and increased the AUC0-∞ ratios of M-IV and M-III to pioglitazone by 44% (P = 0.0011) and 32% (P = 0.0027), resp. Rifampicin increased the M-IV/pioglitazone and M-III/pioglitazone ratios in urine by 98% (P = 0.0015) and 95% (P = 0.0024). A previously unrecognized metabolite M-XI, tentatively identified as a dihydroxy metabolite, was detected in urine during both phases, and rifampicin increased the ratio of M-XI to pioglitazone by 240% (P = 0.0020). Conclusions Rifampicin caused a substantial decrease in the plasma concentration of pioglitazone, probably by induction of CYP2C8. Concomitant use of rifampicin with pioglitazone may decrease the efficacy of the latter drug.

DOCUMENT TYPE: Journal
LANGUAGE: English
AB Objective: Our objective was to study the effects of gemfibrozil on the pharmacokinetics of pioglitazone and the active compds., which are all the substrates of CYP2C8 and CYP3A4. Methods: In a randomized, two-phase crossover study, 10 healthy volunteers were pretreated for 2 days with either 600 mg oral gemfibrozil or placebo twice daily. On day 3, they received a single dose of 600 mg gemfibrozil or placebo, and 1 h later they received a single oral dose of 30 mg pioglitazone. Plasma concns. of

pioglitazone and both active metabolites M-III and M-IV were measured for up to 120 h. Results: Gemfibrozil raised the mean total area under the concentration-time curve (AUC) of parent pioglitazone 3.4-fold (P<0.001). No statistically significant changes were seen in the total AUC of M-III or M-IV after gemfibrozil pretreatment. Gemfibrozil reduced the M-III/pioglitazone and M-IV/pioglitazone AUC0-∞ ratio by 71% (P<0.001) and 65%(P<0.001), strikingly prolonging their t1/2. Conclusion: Gemfibrozil greatly increased the plasma concentration of parent pioglitazone and also inhibited the further metabolism of M-III and M-IV. Careful blood glucose monitoring and dosage adjustments are suggested during coadministration of pioglitazone and gemfibrozil.

AB This study assessed the single- and multiple-dose pharmacokinetics of 3 doses (15 mg, 30 mg, and 45 mg) of pioglitazone in 36 adolescents with type 2 diabetes. Blood samples were obtained over a 48-h interval after the first dose (day 1) and over a 72-h interval after the last dose (day 15) of pioglitazone and were assayed for pioglitazone and active metabolites (M-III and M-IV). Pioglitazone systemic exposure increased dose dependency but was less than dose proportional during multiple

dosing. The median peak pioglitazone concentration occurred at 2 h. The mean half-life was 8 to 9 h for pioglitazone and 24 to 32 h for M-III and M-IV, with similar values at each dose level. During multiple dosing, accumulation for pioglitazone was negligible, but it reached 2.5- to 3.0-fold for M-III and M-IV. The sustained total serum concentration of active compds. during multiple dosing provides the basis for once-daily dose administration of pioglitazone in adolescents.

AB The present invention discloses a novel and general process to prepare various pyridine substituted 5-[4-[2-(alkyl substituted pyridyl)ethoxy]benzyl]-2,4-thiazolidinone derivs. of general formula I [R = alkyl], and their pharmaceutically acceptable salts. The present invention especially provides a novel process to prepare pioglitazone hydrochloride [R = 5-ethyl], via novel intermediates, i.e. II and III. This process involves lesser number of steps with high yields and uses key solid intermediates, which are operationally simple, and therefore offers opportunities for better com. viability.

AB Clin. studies have suggested that Pioglitazone, an insulin sensitizer, has a stronger effect in women than in men. To determine the sex difference in the pharmacokinetics of Pioglitazone, the authors examined the plasma and white adipose tissue levels of Pioglitazone and its active metabolites (M-II, M-III, and M-IV) in male and female rats treated with a single or repeated oral administration of Pioglitazone (10 mg/kg). The AUCs of Pioglitazone (149.6±22.6 vs. 103.3±14.0 μg·h/mL; P<0.01), M-III (31.4±8.1 vs. 20.2±4.7 μg·h/mL; P<0.05), and M-IV (41.9±15.5 vs. 14.1±1.6 μg·h/mL; P<0.01) were larger in female rats than in male rats, but the levels of M-II were similar. Any of the compds. did not accumulate in plasma after repeated administration. According to kinetic model anal., the apparent elimination rate of Pioglitazone and the formation rate of M-II were faster in male rats than in female rats. No significant sex difference was found in the tissue-to-plasma concentration ratios of Pioglitazone or its active metabolites in white adipose tissue. These results suggest that there are sex differences in the plasma levels of Pioglitazone and some of its active metabolites and that those differences are reflected in differences in white adipose tissue levels.

AB Four new metabolites of pioglitazone were identified by liquid chromatog.-mass spectrometry (LC-MS/MS) as being formed by hydroxylation (M-VII and M-VIII), opening of the thiazolidinedione ring (M-X) and by desatn. of the terminal Et side chain or tether ethoxy moiety (M-IX), resp. The structure of one of the hydroxylated metabolites (M-VII) was confirmed by chemical modification using the Jones reaction. Oxidative cleavage of the thiazolidinedione ring is a novel pathway not previously reported for pioglitazone. The hydroxylated M-VII was detected in incubations with rat, dog and human liver and kidney microsomes, and in

plasma from rats and dogs dosed orally with [3H]pioglitazone. The carboxylic acid derivative of M-VII (M-V) and its taurine conjugate were the major radioactive components in dog bile.

AB An efficient six-step synthesis was developed for the preparation of the thiazolidinedione analog PNU-91325 from a com. available olefin. This process involves a novel epoxide ring opening with a deactivated phenol under phase-transfer conditions. Significant improvements were made in the oxidation of a secondary alc. to the ketone and the 1,4-reduction of an enone from a previous process. Overall, this route allows for the preparation of PNU-91325 in 25% yield.

AB It has been demonstrated that antidiabetic thiazolidine and oxazolidine derivs. (glitazones) exhibit novel effects on apoptosis of cardiomyocytes. These substances are capable of greatly decreasing apoptosis by a pathway that is not Caspase 3 dependent. Addition of IGF1 to the treatment further prevents apoptosis. Glitazones alone or glitazones plus IGF1 should be administered at the beginning of a myocardial infarction and continued through the recuperation period to reduce morbidity and prevent unfavorable remodeling of the myocardium. Thus, troglitazone (5 μM), when added to a culture medium, reduced doxorubicin-induced apoptosis of cardiomyocyte by approx. 60%.

AB A three-dimensional quant. structure activity relationship study (3-D-QSAR) was performed on a set of thiazolidinedione antihyperglycemic agents using the comparative mol. field anal. (CoMFA) method. The CoMFA models were derived from a training set of 53 compds. Fifteen compds., which were not used in model generation were used to validate the CoMFA models. All the compds. were superimposed to the template structure by atom-based and shape-based strategies. The SYBYL QSAR rigid body field fit was also used for aligning the ligands. A total of twelve different alignments were generated. The resulting models exhibited a good cross-validated rcv2 values (0.624-0.764) and the conventional r2 values (0.689-0.921). A more robust cross-validation test using cross-validation by 2 groups (leave half out method) was performed 100 times to ascertain the predictiveness of the CoMFA models. The mean of rcv2 values from 100 runs ranged from 0.611-0.690. Few models exhibited good external predictivity. These models were then used to define a hypothetical receptor model for antihyperglycemic agents.

AB The disposition of pioglitazone was studied after oral administration to rats, dogs, and monkeys using 14C-labeled drug. After oral dosing, pioglitazone was well absorbed from the gastrointestinal tract at an extent of 96, 95, and 90% in rats, dogs, and monkeys, resp. In rats, the concentration of pioglitazone in plasma reached a peak (Cmax 0.71 μg/mL) at 4 h (tmax) after dosing and declined with a half-life (t1/2) of 2.6 h. In dogs, tmax, Cmax and t1/2 were 0.5 h, 0.32 μg/mL and 2.1 h, and those for monkeys were 4.3 h, 0.48 μg/mL and 5.3 h, resp. The drug was metabolized mainly to M-I to M-VI including the pharmacol. active metabolites (M-II, III, and IV). The pharmacol. active compds. (total of the unchanged compound and the above three active metabolites) accounted for 87, 71 and 73% of the radioactivity in plasma of rats, dogs, and monkeys, resp. The radioactivity was widely distributed in tissues after oral administration to rats, and decreased to the very low concentration within 24 to 72 h after dosing. Radioactivity dose was almost completely excreted in urine and feces.

AB Metabolic studies of pioglitazone,, a new antidiabetic agent, in rats and dogs using liquid chromatog./tandem mass spectrometry and 1H-NMR led to characterization of the following metabolites: the parent compound, (±)-5-(p-hydroxybenzyl)-2,4-thiazolidinedione (M-I), (±)-5-[p-[2-(5-ethyl-2-pyridyl)-2-hydroxyethoxy]benzyl]-2,4-thiazolidinedione (M-II), (±)-5-[p-[2-(5-acetyl-2-pyridyl)ethoxy]benzyl]-2,4-thiazolidinedione (M-III), (±)-5-[p-[2-[5-(1-hydroxyethyl)-2-pyridyl]ethoxy]benzyl]-2,4-thiazolidinedione (M-IV), (±)-5-[p-[2-(5-carboxymethyl-2-pyridyl)ethoxy]-benzyl]-2,4-thiazolidinedione (M-V), and (±)-5-[p-[2-(5-carboxy-2-

pyridyl)ethoxy]benzyl]-2,4-thiazolidinedione (M-VI). Pioglitazone is considered to be metabolized by cleavage of aliphatic C0 bond to lead to M-I, hydroxylation of aliphatic methylene groups to form M-II and M-IV, oxidation of M-IV to give M-III, oxidation of the Et group to form M-V, and oxidative loss of the terminal carbon to lead to M-VI. Furthermore, part of metabolites exist as conjugated form. Among the conjugates, M-IV conjugated with sulfuric acid and M-V conjugated with taurine were identified.

I

AB The disposition of AD-4833 (I) was studied after oral administration to mice, rats, dogs, and monkeys, using [14C]AD-4833-HCl. Concns. of AD-4833 in mouse plasma attained a peak (Cmax, 0.51 μg/mL) 1.0 h (Tmax) after administration and declined with an apparent half-life (t1/2) of 3.1 h. Concns. of AD-4833 in rat plasma attained a peak (Cmax, 0.71 μg/mL) 4.0 h (Tmax) after administration and declined with t1/2 of 2.6 h. Tmax, Cmax, and t1/2 in dogs were 0.5 h, 0.32 μg/mL, and 2.1 h, resp., and those in monkeys were 4.3 h, 0.48 μg/mL, and 5.3 h, resp. The bioavailabilities of AD-4833 in mice, rats, dogs, and monkeys were 81, 85, 94, and 81%, resp. The pharmacokinetics of AD-4833 in rats and dogs were linear in the dose ranges of 0.5-30 mg/kg and 0.1-3 mg/kg, resp. In rats, the radioactivity was distributed widely in tissues. The concns. of radioactivity in most tissues were lower than those in plasma. The main component in the tissues was the unchanged drug. During repeated administration of [14C]AD-483-HCl for 14 days to rats, the radioactivities in most tissues increased to attain a steady state within the last administration period. After ceasing the administration, 14C levels in tissues declined gradually. The binding of AD-4833 to plasma protein in mice, rats, dogs, and monkeys, and to serum protein in humans, was >98%. The drug was metabolized mainly to 6 compds., three of which were pharmacol. active. The main component in plasma was unchanged AD-4833 in mice, rats, and monkeys, and a metabolite in dogs. Only small amts. of unchanged drug were excreted in the urine and feces of mice, rats, dogs, and monkeys. The excretion of radioactivity in urine and feces was almost complete within 72, 72, 96, and 168 h in mice, rats, dogs, and monkeys, resp. Biliary excretion and enterohepatic circulation were observed in rats. In rats, the radioactivity was excreted quant. within 48 h after the end of repeated administration of [14C]AD-4833-HCl/day for 7 days. 14C was also detected in the milk of rats.

AB The authors have developed improved syntheses of pioglitazone metabolites I, II, III, and IV and the putative metabolite ketone V. These entities have been compared in the KKAy mouse model of human type-II diabetes to

pioglitazone. Ketone V has proven to be the most potent of these thiazolidinediones in this in vivo assay. When I-V were compared in vitro in the 3T3-L1 cell line to pioglitazone for their ability to augment insulin-stimulated lipogenesis, V was again the most potent compound with I, II, and IV roughly equivalent to pioglitazone. These data suggest that metabolites I, II, and IV are likely to contribute to the pharmacol. activity of pioglitazone, as had been previously reported for ciglitazone.

AB A high-performance liquid chromatog. (HPLC) method for the simultaneous determination of pioglitazone (U-72107) and its potential metabolites (M-1 to M-6) in human serum was developed. The method involved a solid phase extraction (SPE) of pioglitazone, its metabolites, and the internal standard (U-92573) from serum using C18 SPE columns with an elution solvent of 0.5 mL of acetonitrile-water (35:65, volume/volume). Separation of the eight analytes was achieved within 20 min using a reversed-phase Zorbax RC-C8 anal. column

(250 mm + 4.6 mm i.d., 5 μm particle size) with a mobile phase of acetonitrile-water (40:60, volume/volume) containing 3 mL acetic acid per L mobile phase (apparent pH 5.5). An UV detector operated at 269 nm was used with a linear response observed from 0.02 to 2 μg mL-1 for these analytes except for M-4 which was best fitted with a polynomial regression. Limit of quantitation was 0.02 μg mL-1 for pioglitazone, M-3, M-5, and M-6; 0.04 μg mL-1 for M-2 and M-4; and 0.5 μg mL-1 for M-1 when using a 0.5 mL serum sample for extraction Obtained from the method validation, intra- and inter-assay precision was ≤9% and accuracy ranged from -8.2 to 13.4% for all analytes. The applicability of this method has been demonstrated by successfully analyzing clin. serum samples. The strategies in the HPLC characterization and in the SPE procedure development for this method are discussed as well.

AB The disposition and metabolism of [3H]pioglitazone was determined in male rats after oral administration. The peak plasma concentration of 10 μg/mL occurred 1 h after dosing at 10 mg/kg p.o.; the apparent plasma terminal half-life was 7.5 h. Most of the radioactivity in plasma ≤8 h after dosing was due to the parent drug. Pioglitazone was highly protein-bound in plasma; only 1-2% was free at concns. of 0.1-10 μg/mL. Within 3 days after oral administration to bile duct-cannulated rats, 36% and 15% of the oral dose was recovered in the bile and urine, resp. The pattern of biliary and urinary metabolites was similar. A total of eight metabolites were isolated and identified on the basis of NMR spectroscopy and MS. Metabolites resulting from hydroxylation of either carbon adjacent to the pyridine ring were conjugated with glucuronic acid or sulfuric acid. The metabolite hydroxylated on the terminal carbon of the Et side chain was

further oxidized to the carboxylic acid derivative Oxidative loss of the terminal carbon led to a nicotinic acid derivative and loss of both carbon atoms to the corresponding 3-hydroxypyridine derivative that was excreted as the sulfate conjugate. The two carboxylic acid metabolites were also conjugated with taurine.

I

AB Title compds. I [X = CH2, CO; Q = Ac, MeCHOR, CH2CO2H; R = H, acyl; or Q = Et when X = CO] were prepared as antidiabetics and hypolipemics. Thus, cyclocondensation of Me 2-bromo-3-[4-[2-[5-(1-methoxymethoxyethyl)-2-pyridyl]ethoxy]phenyl]propionate (preparation given) with thiourea followed by deprotection then acetylation, gave title compound I [X = CH2; Q = Ac] (II). II at 0.005 weight% in chow diet for mice gave 56% reduction in blood sugar level and 43% reduction in plasma lipid level. Tablets containing I were prepared

I

AB The synthesis of a series of title compds. I (R = H, Me, OH; R1 = H, 3-, 5-, 6-Me, 5-Et, 6-CH2OH; R2 = H, OH, CH2OH) is described. I were evaluated for hypoglycemic and hypolipidemic activities in genetically obese and diabetic mice. 2-(2-Pyridyl)alkoxy derivs. were found to have much better hypoglycemic and hypolipidemic activities than 2-(3-pyridyl)- and 2-(4-pyridyl)alkoxy derivs. or even the previously reported compound, ciglitazone. The introduction of a hydroxyl group at the 2-position of the ethoxy chain potentiated the activities. Among the potent compds.,

pioglitazone (AD-4833) was selected as a candidate for further study.

II

AB The title compds. I (R1, R2 = H, alkyl; R3 = H, acyl; n = 0, 1) were prepared Thus, a mixture of 3.2 g the propionate II, 558 mg thiourea, 599 mL NaOAc, and 30 mL EtOH was refluxed for 4 h, 30 mL 6N HCl added, and the resulting mixture refluxed for 16 more hours to give 0.95 g I (R1 = 6-Me, R2 = R3 = H, n = 0). I decreased blood sugar and lipids by 22-53% or 11-58%, resp., in mice. I can be administered in the form of capsules, tablets, powders, etc.
